

Project 1A LSQ Fund Update

Prepared for Professor Phelim Boyle

June 2026

Data & Method

The update uses 113 monthly LSQ observations from January 2017 through May 2026. The original paper used 109 observations ending in January 2026; the added LSQ returns are Feb 2026 = 1.88%, Mar 2026 = 3.68%, Apr 2026 = 2.95%, May 2026 = 7.64%. The LSQ analysis uses the baseline net-of-fees return series from the Spartan monthly performance PDF.

For the benchmark, I used the Yahoo Finance `^SP500TR` S&P 500 Total Return Index. This is the appropriate S&P 500 series because the paper states that the benchmark returns are calculated with dividends reinvested; a price-only S&P 500 index would omit dividends and understate the benchmark return.

For 2026-05, the market comparators are pulled from Yahoo Finance monthly adjusted levels. The S&P 500 TR return is 5.263305%, and the NVIDIA return is 5.797466%.

All return inputs are monthly. Population standard deviation divides by N . Sharpe ratios use a 0% risk-free rate. Sortino ratios use the paper's downside-deviation convention. Omega is computed as $\sum \max(r_t - L, 0) / \sum \max(L - r_t, 0)$. Alpha and beta are estimated from the monthly regression of LSQ returns on S&P 500 Total Return Index returns.

Updated Table 2

Table 2: Comparison of LSQ returns with S&P 500 returns

Metric	LSQ	S&P 500 Index
<i>Statistical properties of monthly returns</i>		
Average (arithmetic) return	3.50	1.33
Average (geometric) return	3.42	1.22
Percent Positive Months	95.58	70.80
Percent Negative Months	4.42	29.20
Average Positive Months	3.70	3.62
Average Negative Months	-0.87	-4.22
Best Month	21.97	12.82
Worst Month	-2.20	-12.35
<i>First four moments of distribution of monthly returns</i>		
Mean	3.50	1.33
Standard deviation	3.99	4.52
Skewness	2.61	-0.44
Excess kurtosis	8.09	0.44
<i>Risk adjusted performance metrics</i>		
Sharpe Ratio	0.88	0.29
Sortino Ratio	14.36	0.47
Omega Ratio	92.00	2.08
Alpha	3.53	0
Beta	-0.02	1

Note: Returns are monthly percentages except ratios, skewness, excess kurtosis, and beta. The LSQ column uses the baseline net-of-fees series. The S&P 500 benchmark is the total return index, consistent with the paper's dividend-reinvestment convention.

Updated Table 4

Table 4: Monthly Return Statistics: LSQ Fund, NVIDIA, and Fairfield Sentry			
Statistic	LSQ Fund <i>Jan 2017 to May 2026</i> (<i>N = 113</i>)	NVIDIA <i>Jan 2017 to May 2026</i> (<i>N = 113</i>)	Fairfield Sentry <i>Dec 1990 to Oct 2008</i> (<i>N = 215</i>)
<i>Panel A: Return Summary</i>			
Arithmetic Mean Return	3.50	4.85	0.84
Geometric Mean Return	3.42	3.96	0.84
Percent Positive Months	95.58	64.60	92.09
Percent Negative Months	4.42	35.40	7.44
Average Positive Month	3.70	12.37	0.93
Average Negative Month	-0.87	-8.89	-0.17
Best Month	21.97	38.40	3.29
Worst Month	-2.20	-32.02	-0.64
<i>Panel B: First Four Moments</i>			
Mean (μ)	3.50	4.85	0.84
Standard Deviation (σ)	3.99	13.47	0.711
Skewness	2.61	-0.05	0.79
Excess Kurtosis	8.09	0.07	0.51
<i>Panel C: Risk-Adjusted Ratios (Monthly, risk free rate = 0)</i>			
Sharpe Ratio	0.88	0.36	1.18
Sortino Ratio	14.36	0.68	12.76
Omega Ratio	92.00	2.54	67.32

Sortino uses Estrada (1999) downside deviation: $\sigma_d = \sqrt{\frac{1}{N} \sum_{r_t < 0} r_t^2}$. Omega = $\sum \max(r_t, 0) / \sum \max(-r_t, 0)$.
Fairfield Sentry data: Bernard & Boyle (2009), *Journal of Derivatives*.

Summary of Changes

Table 2: Paper Values vs Updated Values

Metric	Paper	Updated	Change
LSQ arithmetic monthly return	3.48%	3.50%	+0.02 pp
LSQ geometric monthly return	3.40%	3.42%	+0.02 pp
LSQ percent positive months	95.40%	95.58%	+0.18 pp
LSQ percent negative months	4.60%	4.42%	-0.18 pp
LSQ population standard deviation	4.06%	3.99%	-0.07 pp
LSQ Sharpe ratio	0.86	0.88	+0.02
LSQ Sortino ratio	13.96	14.36	+0.40
LSQ Omega ratio	88.28	92.00	+3.72
Alpha, monthly	3.52%	3.53%	+0.01 pp
Beta	-0.04	-0.02	+0.02

Table 4: Paper LSQ Column vs Updated LSQ Column

Statistic	Paper LSQ	Updated LSQ	Change
Arithmetic Mean Return	3.47	3.50	+0.03
Geometric Mean Return	3.40	3.42	+0.02
Percent Positive Months	95.41	95.58	+0.17
Percent Negative Months	4.59	4.42	-0.17
Average Positive Month	3.68	3.70	+0.02
Average Negative Month	-0.87	-0.87	+0.00
Standard Deviation	4.06	3.99	-0.07
Sharpe Ratio	0.86	0.88	+0.02
Sortino Ratio	13.96	14.36	+0.40
Omega Ratio	88.28	92.00	+3.72

Interpretation

The updated LSQ statistics move only moderately because 4 months are being added to a 109-month sample. All added LSQ months are positive, so the number of positive months rises from 104 to 108 and the number of negative months remains five. The average monthly return rises relative to the paper because May 2026 is a strong positive month. The maximum drawdown remains -2.20% because none of the added months creates a new trough.

The risk-adjusted metrics remain very strong. The Sharpe ratio is 0.88, the Sortino ratio is 14.36, and the zero-threshold Omega ratio is 92.00. The updated monthly alpha is 3.53% and beta is -0.02, so the evidence still supports the paper’s conclusion that LSQ’s returns are not explained by broad equity-market exposure.

Additional Analysis: Serial Correlation

Since the paper already identifies serial correlation as an important feature of the LSQ return series, I implemented a serial-correlation diagnostic table and a Newey-West adjusted inference table. Newey-West inference adjusts the standard errors for autocorrelation and heteroskedasticity in the regression residuals. This gives a more appropriate t-statistic when monthly returns are not independent over time.

Serial-Correlation Diagnostics

Table 5: Serial-Correlation Diagnostics for Monthly Returns

Series	ρ_1	LB p(1)	LB p(6)	LB p(12)
LSQ Fund	0.35	0.0002	0.0001	0.0001
S&P 500 TR	-0.14	0.1370	0.5007	0.3521
LSQ minus S&P 500 TR	0.01	0.8885	0.9880	0.8567

ρ_1 is the first-order monthly autocorrelation. LB p(k) is the Ljung-Box p-value through lag k .

Newey-West Adjusted Inference

Table 6: Conventional vs Newey-West Inference

Statistic	Estimate	OLS SE	OLS t-stat	Newey-West SE	Newey-West t-stat
LSQ monthly mean	3.50%	0.38%	9.27	0.53%	6.57
Monthly alpha	3.53%	0.39%	8.93	0.59%	5.98
Beta	-0.02	0.08	-0.27	0.11	-0.21

Newey-West standard errors use 4 monthly lags, based on the rule $\lfloor 4(T/100)^{2/9} \rfloor$ with $T = 113$. The alpha-beta regression is $r_{\text{LSQ},t} = \alpha + \beta r_{\text{S\&P500TR},t} + \varepsilon_t$.

The Newey-West adjustment increases the standard errors, which is expected when there is positive serial correlation. Even after this adjustment, the LSQ monthly mean and alpha remain economically large and statistically strong. The beta remains close to zero and statistically insignificant.

Additional Suggestions

I think the most logical next extension would be to apply the same dependence-aware approach to the paper’s nonlinear performance ratios. We could produce confidence intervals for the Sharpe, Sortino, and Omega ratios without assuming independent monthly observations. This should directly address the serial-correlation issue and preserve our focus on asymmetric performance.
